### Abstract

This study sought to synthesise evidence from published literature on the various learning style preferences of undergraduate nursing students and to determine the extent they can play in promoting academic success in nursing education of Namibia. A comprehensive literature search was conducted on electronic databases as a part of the systematic review. Although, kinaesthetic, visual and auditory learning styles were found to be the most dominant learning style preferences, most studies (nine) indicated that undergraduate nursing students have varied learning styles. Studies investigating associations of certain demographic variables with the learning preferences indicated no significant association. On the other hand, three studies investigating association between learning styles and academic performance found a significant association. Three studies concluded that indeed learning styles change over time and with academic levels. The more nurse educators in Namibia are aware of their learning styles and those of their students, the greater the potential for increased academic performance.

**Keywords:** learning styles; undergraduate nurse student; Namibia; academic performance

# Background

In the realm of nursing education, learning styles have been at the centre of investigation for the past decade. The importance of learning styles potentially varies by subject or profession. Identifying learning style preferences in nursing students has the potential of helping nursing educators to improve on their teaching styles and to adapt to the diversity in learning styles (Alharbi et al. 2017). Bangcola (2016) revealed that each

Africa Journal of Nursing and Midwifery https://upjournals.co.za/index.php/AJNM/index Volume 21 | Number 1 | 2019 |#5758 | 25 pages https://doi.org/10.25159/2520-5293/5758 ISSN 2520-5293 (Online) © Unisa Press 2019 nursing student is most comfortable in a particular learning style which in turn has an influence on their academic performance.

A number of learning style tools have been used to investigate various learning styles of undergraduate nursing students. The commonly used learning style scales that have been found to be valid and reliable and have frequently been used in nursing education are the VARK Learning Style questionnaire, the Kolb Learning Style Inventory (LSI), Honey and Mumford's (2000) learning style questionnaire, the Myers-Briggs Type Indicator, the Felder-Silverman Learning Style Model, the Perceptual Learning Style Questionnaire, and the Productivity Environmental Preference Survey (PEPS).

### VARK Learning Style Questionnaire

The VARK measures individual learning styles using perceptual preferences (visual, aural/auditory, read/write, kinaesthetic). Visual learners appreciate symbols, which are used to categorise information, aural or auditory learners prefer information to be presented using verbal communication, and are apt to audiotape content presentation, read/write learners use reading and writing as modes of learning and note taking supplements the original instruction, whereas kinaesthetic learners use field trips, role playing, demonstrations, or other activities that provide practice with respect to the information (Lee, Schull, and Ward-Smith 2016).

### Kolb Learning Style Inventory

This scale is an inventory that measures an individual's learning styles based on four modes: Concrete Experience (CE) Reflect Observation (RO), Abstract Conceptualisation (AC) and Active Experimentation (AE) (Gebru, Ghiyasvandian, and Mohammodi 2015). Kolb LSI characterises individuals into one of the four quadrants of a learning style type grid, namely converger, diverger, assimilator and accommodator. Convergers combine AC and AE, have a strong ability to apply an idea practically and are good at problem-solving and decision-making, divergers combine CE and RO, look at problems from all perspectives and have a strong imagination and awareness of meanings and values, assimilators combine RO and AC, and have a strong ability to create theoretical ideas and plans, and accommodators combine CE and AE, engage effectively in new experiences and are interested in carrying out plans and getting the job done (Mitchell, James, and D'Amore 2015).

### Honey and Mumford's Questionnaire

Honey and Mumford use an 80-item questionnaire to assess learning styles based on five categories: activists (concerned with the here and now, they like to experience by taking direct action and participation), reflectors (think about things in detail, observe and evaluate from a range of perspectives before taking action, they appreciate the opportunity to repeat a learning experience), theorists (like to see how things fit into the bigger picture, they adopt a logical, systematic and analytical approach to problem-

solving), and pragmatists (like to see how things work and can be applied to practice, like to experiment and see the relevance of their work and adopt a practical problemsolving approach to situations) (Honey and Mumford 2000).

### **Myers-Briggs Type Indicator**

This scale is designed for group administration and determines learning styles on four dichotomies: extraversion/introversion (you prefer to focus on the outer world or on your own inner world), intuition/sensing (prefer to focus on the basic information you take in or prefer to interpret and add meaning), thinking/feeling (when making decisions you prefer to first look at logic and consistency or first look at the people and special circumstances), and perception/judgement (in dealing with the outside world, you prefer to get things decided or you prefer to stay open to new information and options) (The Myers and Briggs Foundation 2018).

### Felder-Silverman Learning Style Model

This model consists of a 44-item self-report questionnaire focusing on four dimensions: input (visual: pictures, diagrams, graphs, demonstrations, or auditory-words, sounds), perception (sensory (external): sights, sounds, physical sensations, or intuitive (internal): possibilities, insights, hunches), processing (actively: through engagement in physical activity or discussion, or reflectively: through introspection), and understanding (sequentially: in continual steps, or globally: in large jumps, holistically) (Felder and Silverman 1988).

### Perceptual Learning Style Questionnaire

This questionnaire assesses the preferences of student learning styles based on their perceptions utilising 30 self-report statements rated on a five-point Likert scale. The 30 items are distributed equally among the learning style preferences: five items each for statements regarding visual, auditory, kinaesthetic, and tactile preferences, and two social aspects of learning: group and individual preferences. The learning style categories with the most points determine an individual's preference for those categories (Bangcola 2016).

### Productivity Environmental Preference Survey (PEPS) questionnaire

This is a learning style questionnaire that consists of 100 questions identifying 20 learning style elements. The elements include environmental preferences (sound, light, temperature and furniture design), emotional preferences (motivation, conformity, and persistence), social preferences (authoritative persons present, variation, learning alone, in pairs or as a team), and physiological preferences (perceptual strengths such as auditory, visual tactile or kinaesthetic, time-of-day energy levels, need for intake or mobility) (Hallin 2014).

Notwithstanding a number of investigations on learning styles, there is a paucity of literature on how learning styles contribute to academic success in nursing students (Bangcola 2016). The authors observed that nursing educators in Namibia are not conscious of their students' learning styles. Educators often have a tendency to focus solely on instruction, rather than considering learning styles. To the best knowledge of the authors there is no evidence in literature of the preferred learning style of undergraduate nursing students in Namibia and how it contributes to their academic success. Further, it is unknown what role learning styles can play in promoting academic success in Namibia. This study aims to synthesise evidence from published literature on the various learning styles or preferences of undergraduate nursing students and the potential role they can play in promoting academic success in nursing education of Namibia.

# Methods

A systematic review of literature was undertaken on the learning style preferences of undergraduate nursing students for the past 10 years (2007 to 2017). In this study, all English-speaking countries worldwide were included. The search was conducted in January 2018.

# **Research Questions**

To what extent can published literature provide evidence on the various learning style preferences of undergraduate nursing students? Further, what role can learning styles play in promoting academic success in nursing education of Namibia?

The objectives of the study were to identify the most prevalent learning style preferences of undergraduate students and to determine the role that learning styles play in their academic success.

# **Identification of Relevant Studies**

Using the key phrase "learning style preference" to answer the research question, a search was made in English for all peer-reviewed literature in the following electronic bibliographic databases: Google scholar, Pubmed, EBSCOhost (MEDLINE, PsychINFO, Academic search, Education source, Health source), Sage Publications, Science Direct, and Web of Science. Relevant websites were also checked for articles and the reference lists of all included studies were screened to select studies.

Initially the key search phrase was limited to "learning style preference" to obtain a sense of the volume of literature. This initial search was limited to Google Scholar and Pubmed to determine the appropriateness and sensitivity of the key search phrase.

Secondly, to narrow down the search and include the relevant articles, an extensive search was conducted with other databases (EBSCOhost, Sage Publications, Science Direct, and Web of Science) utilising the following search words and phrases: "learning style AND preference AND undergraduate nursing students".

Two independent research personnel, researcher 1 (TS) and researcher 2 (SI) reviewed the retrieved articles. The review and selection process was guided by PICO (Cooke, Smith, and Booth 2012), as shown in Table 1, to screen out studies that did not focus on the research questions. Only articles written in English were included and articles without an abstract were excluded, as the procedure for selecting articles primarily involved reviewing the abstracts. Letters to the editor and short editorials were also excluded.

Where a full article was not available, the main author of the article was contacted to obtain a reprint of the full article as abstracts may not capture the full scope of an article (Badger et al. 2000). Detailed arbitration was followed with each step (Cleaver and Nixon 2014) and the results of this process are shown in Figure 1.

# Methodological Qualitative Rigour

The two independent reviewers utilised the Critical Appraisal Skills Programme (CASP) (Arksey and O'Malley 2005) to assess methodological qualitative rigour of the 18 included articles (see Table 2). The CASP is used to appraise a systematic review attempting to answer the following three broad issues: Are the results of the study valid? What are the results? Will the results help locally? The CASP consists of 10 questions to help reflect on these issues. The first two questions allow for quick screening, and a "yes" answer to both questions allows one to proceed with the remaining questions (Critical Appraisal Skills Programme 2018). There is a degree of overlap in the questions, requesting to answer "yes", "no" or "cannot tell". This checklist does not come with a scoring system and thus this study adapted a scoring system by M'kumbuzi and Myezwa (2016). Table 2 depicts the performance of the 18 included articles on the 10 CASP questions.

| Table 2: Outcomes of | CASP of | questions |
|----------------------|---------|-----------|
|----------------------|---------|-----------|

| 1 Author    | Response    | 1. Did the review address a clearly focused question? | 2. Did the authors look for the right type opapers? | 3. Do you think all the important relevant studies were included? | 4. Did the reviewers' authors do enough t<br>assess the quality of the included studies? | 5. If the results of the review have been combined, was it reasonable to do so? | 6. What are the overall results of the revie | 7. How precise are the results? | 8. Can the results be applied to the local population? | 9. Were all the important outcomes considered? | 10. Are the benefits worth the harms and costs? | Total |

# **Charting the Data**

A "data charting form" using an Excel spreadsheet was utilised to review the final selected 18 original research articles. The second author did a blind verification of a random sample of 20 per cent (4) of the articles to check the quality of the categorisation of the charting process. Inconsistencies in the charting process were resolved through discussion.

Initially, the following categories of information for each study were recorded: year of publication, geographical distribution, academic year of study, learning style scale, study design, and sample size. Secondly, a conventional content analysis (Namey et al. 2008) was undertaken to analyse the purposes, outcomes, implications and areas for future research. This process involved reviewing the articles and highlighting text that appeared to describe these four areas. These data were extracted verbatim for coding and the final codes (themes) were examined, followed by a tabulation of frequencies of each theme.

### Results

The initial search yielded 3 554 articles of which 3 516 did not meet the inclusion criteria and 38 were retained for review. A final 18 full-text articles were included for review. Based on the performance of the 18 included articles on the 10 CASP questions, it was difficult to tell if the results are applicable to the local population because none of the studies were conducted in Namibia, or anywhere else in Africa (Question 8). However, all the articles were considered to be valuable (Question 10).

Table 3 charts the narrative description of the studies following these categories of information: year of publication, geographical distribution, academic year of study, learning style scale, study design, and sample size.

### Year of Publication

All articles were published from January 2010 to October 2017. The results showed that over this period there was a small, but increasing interest in investigating the learning style preferences of undergraduate nursing students.

### **Demographical Location**

The majority of the studies were conducted in the Middle East (six), with the balance in Australia (four), Asia (three), Europe (two), South America (two), and North America (one). It was observed that no articles published in Africa were found in any of the database searches.

### **Population and Sample**

Half of the studies (nine) included a population of all nursing undergraduate academic levels (year 1–4). Five studies focused only on first-year students, one study on second-year students only, and one study on final-year students only. Two studies compared the learning styles preferences of first-year and final-year students. The sample sizes ranged from 56–345 with most studies (13) utilising a sample size above 100.

#### **Research Design**

The majority of the studies (12) employed a cross-sectional descriptive design, one study utilised prospective correlational study and another study used a longitudinal, descriptive comparative design.

#### Learning Style Scale

The commonly used learning style scales were the VARK Learning Style questionnaire (seven studies) and the Kolb LSI (six studies). Two studies utilised Honey and Mumford's (2000) learning style questionnaire. The Myers-Briggs Type Indicator, the Felder-Silverman Learning Style Model, the Perceptual Learning Style Questionnaire, and the Productivity Environmental Preference Survey (PEPS) questionnaire were utilised once.

| Description         |             | Number   | List of articles ( by authors)   |

One study (Mitchell, James, and D'Amore 2015) used a combination of two scales. Other studies by El-Gilany and Abusaad (2012), Koch et al. (2011), and Shinnick and Woo (2015) combined one learning style scale with a questionnaire.

# **Purposes, Outcomes and Implications of Studies**

Table 4 presents the different purposes that the studies investigated, the outcomes and implications of the studies.

### Purposes

Five main purposes were explored by the studies. The majority of studies explored more than one purpose. Ten of the studies aimed at identifying learning style preferences, while eight investigated associations of certain demographic variables with the learning preferences. The association between learning styles and academic performance was investigated by six studies, while four examined changes in students' learning styles over time. Noteworthy is that one study analysed the link between learning preference and language proficiency.

#### Outcomes

Although, kinaesthetic, visual and auditory preferences were found to be the most dominant learning style preferences, most studies (nine) indicated that undergraduate nursing students have varied learning styles.

The seven studies investigating associations of certain demographic variables with the learning preferences indicated no significant association. On the other hand, the three studies investigating the association between learning styles and academic performance found a significant association. Three studies concluded that indeed learning styles change over time and with academic levels.

### Implications of the Studies

Several implications for practice for each outcome are indicated in Table 4. For example, Bangcola (2016) urged teachers to be cognisant of the efficacy of more learning styles that allow students to achieve optimal learning.

| Purpose<br>identified          | No of<br>studies | Outcomes          |                                     | No of<br>studies | Implications for practice  |

### Discussion

Given the increasing interest in investigating the learning style preferences of undergraduate nursing students, this review did not find any conducted in Africa. The authors assume that there are numerous studies going on in Africa, but that they are possibly not documented in peer-reviewed journals. Fleming, Mckee, and Huntley-Moore (2011) argued that knowledge and practise in nursing profession are not static, but ever-changing. Nurse educators are encouraged to upgrade their delivery of instruction to match the student abilities and learning styles (Bangcola 2016). To this end, there is a need for more funding for investigating learning style preferences of undergraduate nursing students that could be shared with the wider community, ensuring the evolution and growth of nursing education. Further, nursing educators need to document their studies in peer-reviewed journals regarding the learning styles of undergraduate nursing students.

Kinaesthetic, visual and auditory learning styles were found to be the most preferred learning styles, suggesting the need for more hands-on laboratory work, demonstrations, simulations, videos, etc. Understanding the predominant learning style has the potential to guide the development of the curriculum and teaching strategies (Gebru, Ghiyasvandian, and Mohammodi 2015). However, other studies recorded low scores with aural learning styles, indicating that the traditional method of teaching with PowerPoint presentations and lectures is not preferred by modern students (James, D'Amore, and Thomas 2011). Although the kinaesthetic, visual and auditory learning styles were found to be the most preferred learning styles, most students had more than

one (multimodal) preferred learning style. Educators are encouraged to reflect on their learning style before preparing their lessons (Hallin 2014). However, the authors take cognisance of the fact that some nurse educators might not be aware of the various learning styles that exist. There is a potential for those who are aware of their learning style to be biased towards their preferred learning style resulting in an unbalanced learning environment. Moreover, both learners and educators are encouraged to have an awareness of the available learning styles at the beginning of the course to stimulate a balanced learning environment and to enable learners to grow in learning as they can draw from each learning style (D'Amore, James, and Mitchell 2012).

Noteworthy is that almost all the studies in this review, investigating the association of learning styles with demographic characteristics, found no association. In order to embrace student diversity, educators need to tailor support services and educational strategies for student learning needs (Li et al. 2011). On the other hand, one study (Bangcola 2016) revealed an association between learning styles with demographic characteristics, indicating the need to profile student learning styles at each academic year level. Thus a greater emphasis should be placed on profiling student learning styles at each academic year to ensure academic success. James, D'Amore, and Thomas (2011) observed that cohorts of nursing students are changing and therefore there is a need to profile all fresh entry students. This will allow for individual tutorials to be tailor-made for students who are having challenges in grasping concepts.

The reviews also found that there is an association between a learning style and academic performance. A study of Australian nursing students revealed that a strong kinaesthetic mode was a predictor of academic success (Koch et al. 2011). Similarly, a study in China on nursing students affirmed that academic success is significantly related to learning style (Yi et al. 2014). However, Rassool and Rawaf (2007) stated that a mismatch between the student and educator learning style can hamper success as students lose interest in the subject, do poorly on tests or exams, and might give up as they conclude that they are no good at the subject. Importantly, educators should note that each academic year has new courses and presents different challenges. Thus each academic level curriculum should be aligned to the student learning styles as learning style preferences change over time.

Critical to nursing education is language proficiency. Evidence has shown that there is a link between a learning preference and language proficiency. James, D'Amore, and Thomas (2011) found that students who spoke English had high mean values compared to those who are non-English speaking. Thus, nursing educators in Namibia may need to embrace the diversity of English proficiency for students who are school-leavers or mature entry, from rural and urban backgrounds and from English and non-English speaking backgrounds.

The researchers premised the selection of systematic review as a choice of methodology based on the fact that they synthesise knowledge that is essential to advance practice

and research through consolidation of evidence. Systematic reviews are aimed at informing nursing education, programmes, and policy, and providing direction to future research priorities. Systematic reviews can be utilised to answer a range of research questions and to reveal research gaps. Evidence indicates that they can also help enhance knowledge of research methods and improve research productivity.

### Limitations

Although multiple electronic databases were searched, the search could have been more comprehensive had social science databases been included. Further, including only English articles could have excluded important articles. Future searches could potentially include social science databases and articles in a variety of languages.

# Conclusion

Despite some studies indicating that the most preferred learning styles of undergraduate nursing students are primarily kinaesthetic, visual or auditory learning styles, the majority concluded that they are multimodal learning styles. Nurse educators need to embrace diversity in student backgrounds and demographic characteristics to foster an environment conducive to learning. The current study revealed that there is a significant association between learning style preferences and academic performance and thus it is critical to investigate student learning style preferences to ensure improved curriculum development and teaching methods aimed at increasing academic success. The more educators in Namibia are aware of learning style, their own learning styles and the learning styles of their students, the greater the prospects are for increased student academic performance. Several recommendations for future research were identified (as shown in Table 5).
